

ABSTRACT OF THE DISCLOSURE

The system has a A speech recognizer (2) for recognising recognizer recognizes speech from a user and a synthesizer (6) for replying synthesizer replies to him the user and engages in a dialogue with the object of enabling the user to convey to the system a piece of information such as a telephone number. The system builds up the number in a buffer (10). Each time it receives a string of digits, it reads it back for confirmation. When a number (or part of one) is read back, it is divided into "chunks" according to certain criteria: the positions of these divisions can be recorded to be taken into account in later processing. Responses are compared with the current buffer contents to determine whether they is such should be interpreted as a correction, partial correction or pure continuation of the existing contents. Positions in the buffer at which pure continuations are entered are marked, to allow a "final repair" process in which, if the final result fails to match some criterion of acceptability (e.g., length) the marked positions can be reexamined to determine whether interpretation instead as of correction or partial correction would meet the criterion. Algorithms are described for comparing compare new input with digits already received, to decide how it is to be interpreted.
